

# Automated Evaluation of Programming Assignments – from Practice to Research

Sujit Kumar Chakrabarti

IIITB

January, 2020

# Outline for section 1

- 1 An Automated Evaluation System
- 2 Approaches to Automated Evaluation
- 3 Static Analysis
- 4 Static Analysis + Machine Learning
- 5 Wrap Up

# Credits

- Nikhila – PhD student
- Ananta – MS/R student
- Kapil Kalra – summer intern, 2018
- Manish Gupta – Professor (IIIT-B), Google AI Research Lab
- Many students, TAs, project/thesis students, interns

# Why Automated Evaluation?

- Online learning platforms: Coursera, Udacity, EdX ...
- Online programming contests: ACM ICPC, HackerEarth, HackerRank, CodeChef ...
- Introductory programming courses
- Error prone, labour intensive, repetitive

# Why Automated Evaluation?

- Online learning platforms: Coursera, Udacity, EdX ...
- Online programming contests: ACM ICPC, HackerEarth, HackerRank, CodeChef ...
- Introductory programming courses
- Error prone, labour intensive, repetitive – *Boring!*

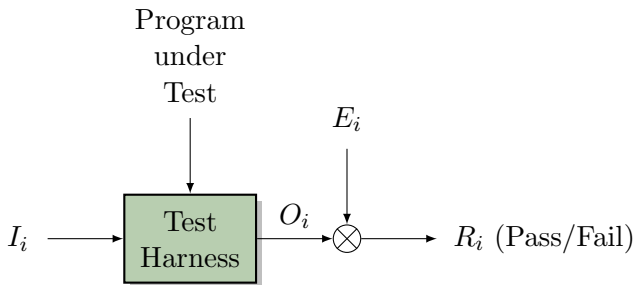

# Our Contribution

## Automated Evaluation System

- Automatically evaluates programming assignments using testing
- Several human weeks → a few seconds
- Has enabled more frequent, deeper formative assessments with shorter feedback cycles

# Testing

## A Test Setup

$I_i$	Test input
$E_i$	Expected output
$O_i$	Actual output
$R_i$	Test result

## Assigning Marks:

$$M = \sum k_i R_i$$

# Test Case

## Example

```
def eval_triangle_area():  
  
    import mycode.pentagon  
    import code.pentagon  
  
    t1 = mycode.pentagon.Triangle(5, 10)  
    t2 = code.pentagon.Triangle(5, 10)  
  
    eo = t1.area()  
    ao = t2.area()  
  
    if(equals(ao, eo)):  
        return (1, "eval_triangle_area")  
    else:  
        return (0, "eval_triangle_area: wrong answer")
```

Test case to check if a triangle's area is computed properly

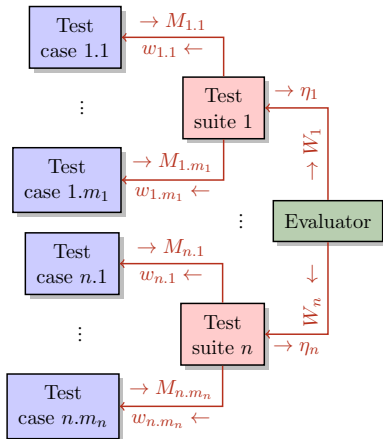

# System Architecture

$$\eta = \frac{\sum w M}{\sum w}$$

$$total = \sum \eta W$$

# System Architecture

$$\eta = \frac{\sum w M}{\sum w}$$

$$total = \sum \eta W$$

# AEPA System

## Achievements

- 1 Simple setup – no server (except LMS)
- 2 Simple use – on local machine
- 3 Flexibility
- 4 Language independent
- 5 All data is readily available
- 6 Knowledge creation
- 7 Software offering

# Outline for section 2

- 1 An Automated Evaluation System
- 2 Approaches to Automated Evaluation**
- 3 Static Analysis
- 4 Static Analysis + Machine Learning
- 5 Wrap Up

# Approaches to Automated Evaluation

- Testing
- Testing + Static Analysis
- Static Analysis
- Testing + Static Analysis + Machine Learning

# Testing

## Advantages:

- 1 Conceptually simple
- 2 Easy to automate

# Testing

## Advantages:

- 1 Conceptually simple
- 2 Easy to automate

## Issues:

- 1 Fragility
- 2 Designing the comparator
- 3 Testing structural properties

# Testing

## Issues – Fragility

- 1 Parsing complex outputs – tolerating minor variability
- 2 Overhead on students to understand the format and code to print output in a the specified format
- 3 Crashes and exceptions
- 4 Infinite loops

## Solutions:

- 1 Running  $P$  in a different thread.
- 2 Wrapping  $P$  in input/output script and then executing

# Testing

## Issues – Testing Structural Properties

### Examples:

- Has the factorial function been implemented using recursion or loop?
- Quicksort or mergesort?
- ...

# Testing + Static Analysis

## Basic Idea:

To use reflection to navigate through the abstract syntax tree of the program?

## Example:

```
@evaluate
def eval_square_baseclass():
    import code.pentagon
    s = code.pentagon.Square(10)
    base_names = [c.__name__ for c in s.__class__.__bases__]
    if(base_names == ["RegularPolygon"]):
        return (1, "eval_square_baseclass")
    else:
        return (0, "eval_square_baseclass: wrong answer")
```

# Testing + Static Analysis

## Issues

- The static properties that can be tested is dependent on the depth of reflection offered by the programming language. For example, in C++, how to check if class *B* is subclass of class *A*?
- Some properties are not easy to test; require more full-fledged static analysis. For example, how to test if a variable used has been defined earlier or not?

# Outline for section 3

- 1 An Automated Evaluation System
- 2 Approaches to Automated Evaluation
- 3 Static Analysis**
- 4 Static Analysis + Machine Learning
- 5 Wrap Up

# Static Analysis

## Basic Approach

# Static Analysis

Issues – Partially correct submissions

## Example

**Q.** Write a program that finds the transverse of a matrix (represented as a list of lists).

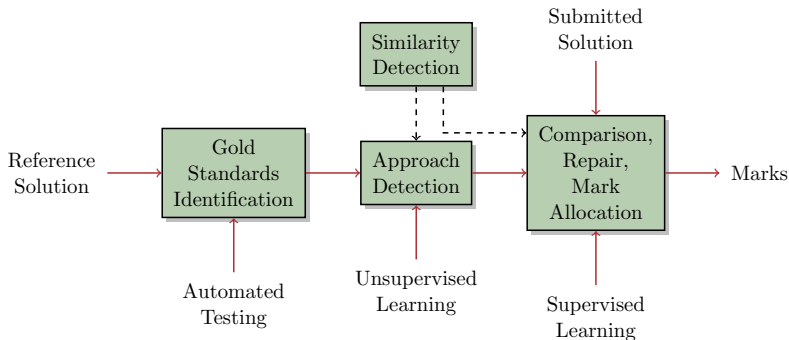

```
m = [ [1, 2, 3], [4, 5, 6] ]
n = []
for i in range(len(m[0])):
    row = []
    for j in range(len(m)):
        row.append(m[j][i])
    n.append(row)
print n
```

# Outline for section 4

- 1 An Automated Evaluation System
- 2 Approaches to Automated Evaluation
- 3 Static Analysis
- 4 Static Analysis + Machine Learning**
- 5 Wrap Up

# Static Analysis + Machine Learning

## Basic Approach

# Outline for section 5

- 1 An Automated Evaluation System
- 2 Approaches to Automated Evaluation
- 3 Static Analysis
- 4 Static Analysis + Machine Learning
- 5 Wrap Up**

# Conclusions

## Summary

- A home-grown automated evaluation system
- Approaches and challenges in automated evaluation
- Static analysis
- Static analysis + machine learning

Thank you!

Thank you!
